Abstract

The complete UV-divergent contribution to the one-loop 1PI four-point function of Yang-Mills theory in the light-cone gauge is computed in this paper. The formidable UV-divergent contributions arising from each four-point Feynman diagram yield a succinct final result which contains non-local terms as expected. These nonlocal contributions are consistent with gauge symmetry, and correspond to a nonlocal renormalization of the wave function. Renormalization of Yang-Mills theory in the light-cone gauge is thus shown explicitly at the one-loop level.

1 Introduction

Ever since the discovery [1–4] of the n_μ^* -prescription for the unphysical poles of $(q \cdot n)^{-1}$ in 1982, the noncovariant light-cone gauge has gained in usefulness and respect. In fact, there can be little doubt that the light-cone gauge, defined by $n \cdot A^a(x) = 0$, $n^2 = 0$, with $n_\mu = (n_0, \mathbf{n})$ a constant vector, $n_\mu^* = (n_0, -\mathbf{n})$, and $n \cdot n^* = 1$, is the most popular of the axial-type gauges.

The light-cone gauge possesses a number of appealing features: it picks out the physical degrees of freedom, its prescription allows a Wick rotation, and the Faddeev-Popov ghosts either decouple from the associated gauge field, or prove harmless in a perturbative setting. Moreover, the light-cone gauge often proves more effective than a covariant gauge (such as the Feynman gauge, or Landau gauge) in sophisticated models like supersymmetric Yang-Mills and superstrings. By exploiting the special features of the light-cone gauge, Brink, Lindgren and Nilsson [5], as well as Mandelstam [1], succeeded in demonstrating that the $N = 4$ supersymmetric Yang-Mills model is UV convergent to all orders of perturbation theory, while Green and Schwarz [6] showed that superstring theory was anomaly-free for the semi-simple Lie groups $E_8 \times E_8$ and $\text{Spin } 32/Z_2$.

An important question that was immediately raised after the discovery of the n_μ^* -prescription, was whether the light-cone gauge was renormalizable to all orders. In view of the technical idiosyncrasies of the light-cone gauge Feynman integrals [7] generally, and the appearance of UV divergent *nonlocal* expressions in both the gluon self-energy and the vertex functions, the question was highly non-trivial. During the ensuing years, the renormalization structure of Yang-Mills theory in the light-cone gauge was examined by several researchers, including Bassetto [8,9], Bassetto and his co-workers [10–13], Lee and Milgram [14,15], Andraši, Leibbrandt and Nyeo [16], Leibbrandt and Nyeo [17,18], and Nyeo [19–21].

It is well known that the presence of non-polynomial divergences in the light-cone gauge greatly complicates the renormalization procedure. The reason is that these non-polynomial divergences automatically require non-polynomial counterterms and, at least initially, it appears that one can construct infinitely many non-polynomial tensor structures that are consistent with dimensional analysis and the Ward identities. Fortunately, there exist further constraints on the possible forms of nonlocal divergences (see Section 5). Using these constraints, Bassetto, Dalbosco and Soldati [22] have predicted the form of the nonlocal divergent density of Γ , the generating functional for 1PI diagrams, from which they derive the nonlocal part of the 1PI four-point function. Their result allows for renormalization using only a finite number of both local and nonlocal structures. In our explicit calculation of the 1PI four-point function

we obtain not only the predicted *nonlocal* tensor structure, but also the local part, as well as their relative weights. It is taken for granted in Bassetto's joint paper that the usual local part occurs as well.

In 1987, Bassetto, Dalbosco and Soldati gave an inductive proof of the renormalizability of massless Yang-Mills by showing [22] that "...despite the appearance of an infinite number of nonlocal divergent terms, the theory can be made finite to any order in the loop expansion by introducing a finite number of renormalization constants...", and, furthermore, that "...the nonlocal structures are completely decoupled from the physical quantities." The authors were guided in their proof by previous loop calculations, but there was one 1PI function which had never been evaluated in the light-cone gauge. This was the infamous 1PI four-point function, containing box, lynx and fish diagrams, which was obviously vital for the explicit completion of the renormalization proof at the one-loop level. Unfortunately, the horrendous algebra inherent in the computation of the 1PI four-point function was such as to discourage its evaluation for many years. Bassetto and his co-workers decided to do the next best thing: by using renormalization arguments, they predicted that the one-loop 1PI four-point function possessed a certain tensorial structure in terms of the free parameters p_μ , n_μ and n_μ^* . Their prediction dealt specifically with the *nonlocal* terms in the theory.

The purpose of this paper is to report that the UV divergent contribution to the one-loop 1PI four-point function in the light-cone gauge has now been computed in its entirety, and that the prediction by Bassetto, Dalbosco and Soldati concerning this function, made over ten years ago, is in fact correct. Our aim here is to explain and summarize the computation of this formidable function.

The article is organized thus. The Feynman rules and mathematical tools are summarized in Sections 2 and 3, respectively. In Section 4 we evaluate the complete four-point function consisting, as we shall see, of three specific sets of "*subdiagrams*", namely the box diagrams (Section 4.1), lynx diagrams (Section 4.2) and fish diagrams (Section 4.3). Only a few of the intermediate results are shown explicitly to convey to the reader the scope and complexity of the calculation. Our final expression for the UV divergent contribution to the 1PI four-point function in the light-cone gauge is presented in Section 5, where we also discuss the role of the nonlocal terms again, in the context of renormalization. Finally, Appendix A contains a selection of intermediate expressions for certain box, lynx and fish diagrams (Eqs. (38), (39) and (40), respectively).

2 Feynman Rules

In the light-cone gauge,

$$n \cdot A^a = 0, \quad n^2 = 0, \quad (1)$$

(the metric signature is $(+, -, -, -)$) the Lagrangian density for $SU(N)$ Yang-Mills theory takes the form

$$L = -\frac{1}{4}F_{\mu\nu}^a F_a^{\mu\nu} - \frac{1}{2\alpha}(n \cdot A^a)^2 + \bar{\eta}^a n^\mu D_\mu^{ab} \eta^b, \quad \alpha \rightarrow 0, \quad (2)$$

where $F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + g f^{abc} A_\mu^b A_\nu^c$ is the gauge field tensor, $\mu, \nu = 0, 1, 2, 3$, and $a, b, \dots = 1, 2, \dots, N^2 - 1$. The covariant derivative is $D_\mu^{ab} = \delta^{ab} \partial_\mu + g f^{abc} A_\mu^c$ and f^{abc} are the group structure constants. The ghost fields, η and $\bar{\eta}$, appear only in closed loops and obey Fermi statistics.

The Yang-Mills gauge field propagator (Fig. 1) reads, for $\alpha = 0$,

$$G_{\mu\nu}^{ab}(q) = \frac{-i\delta^{ab}}{q^2 + i\epsilon} \left[g_{\mu\nu} - \frac{q_\mu n_\nu + q_\nu n_\mu}{q \cdot n} \right], \quad \epsilon > 0. \quad (3)$$

Fig. 1. *Light-Cone Gauge Yang-Mills Propagator*

The ghost-ghost-gluon vertex is given by

$$U_\mu^{abc}(p, q, r) = -ig f^{abc} n_\mu \delta^4(q + p - r), \quad (4)$$

so that any interaction between ghost and gluon involves the contraction of the gluon propagator with n^μ . Thus,

$$n^\mu G_{\mu\nu}^{ab}(q) = \frac{-i\delta^{ab}}{q^2 + i\epsilon} n^\mu \left[g_{\mu\nu} - \frac{q_\mu n_\nu + q_\nu n_\mu}{q \cdot n} \right] = n_\nu - n_\nu - q_\nu \frac{n^2}{q \cdot n} = 0, \quad (5)$$

so that any ghost-gluon interaction term vanishes, since n_μ is light-like. Although the ghost propagator is not needed for the present calculations, we list it here for completeness:

$$G^{ab} = \frac{-i\delta^{ab}}{q \cdot n}. \quad (6)$$

The bare three-gluon vertex (Fig. 2) reads

$$V_{\mu\nu\rho}^{abc}(p, q, r) = -gf^{abc}[(q - r)_\mu g_{\nu\rho} + (r - p)_\nu g_{\mu\rho} + (p - q)_\rho g_{\mu\nu}], \quad (7)$$

Fig. 2. *Three-Gluon Vertex*

and the bare four-gluon vertex (Fig. 3) is

$$V_{\mu\nu\rho\sigma}^{abcd} = -ig^2 [f_{abe}f_{cde}(g_{\mu\rho}g_{\nu\sigma} - g_{\mu\sigma}g_{\nu\rho}) \\ + f_{ace}f_{dbe}(g_{\mu\sigma}g_{\nu\rho} - g_{\mu\nu}g_{\rho\sigma}) \\ + f_{ade}f_{bce}(g_{\mu\nu}g_{\rho\sigma} - g_{\mu\rho}g_{\nu\sigma})]. \quad (8)$$

Fig. 3. *Four-Gluon Vertex*

3 Mathematical Tools

In this section, we shall discuss the technical aspects relevant to the calculation of the four-point function.

We work in the framework of dimensional regularization, where 2ω defines the dimensionality of complex space-time, and recall that massless tadpoles, such as

$$\int d^{2\omega} q \frac{1}{q^2}, \int d^{2\omega} q \frac{1}{q \cdot n}, \int d^{2\omega} q \frac{1}{q^2(q \cdot n)}, \text{etc.} \quad (9)$$

are set to zero.

The spurious poles of $(q \cdot n)^{-1}$ are treated with the n_μ^* -prescription [1–4],

$$\frac{1}{q \cdot n} = \lim_{\epsilon \rightarrow 0} \frac{q \cdot n^*}{(q \cdot n)(q \cdot n^*) + i\epsilon}, \quad \epsilon > 0, \quad (10)$$

which allows a Wick rotation and is consistent with power counting. Note that care must be taken when using power counting arguments, since the degree of divergence α differs for $q_\perp$ and $q_\parallel$, where

$$\begin{aligned} q \cdot n &= q_\parallel \cdot n, \\ q_\perp \cdot n &= 0. \end{aligned} \quad (11)$$

For example, the gauge propagator (3) has a degree of divergence $\alpha = -2$, when $q \rightarrow \infty$ along any direction. However, with respect to large $q_\perp$ behaviour, the covariant part of the propagator has degree of divergence $\alpha_\perp = -2$, while the noncovariant parts carry degree $\alpha_\perp = -1$. When encountering multiple $(q \cdot n)^{-1}$ factors coming from the gauge propagator (3), we shall use the separation formula

$$\frac{1}{q \cdot n(q-p) \cdot n} = \frac{1}{p \cdot n} \left[\frac{1}{(q-p) \cdot n} - \frac{1}{q \cdot n} \right], \quad p \cdot n \neq 0, \quad (12)$$

which helps unveil the nonlocal structure of the UV divergence of the Green functions [23].

The separation formula (12) is applied as many times as is necessary to yield integrals containing only a single noncovariant denominator; a shift in the integration variable k , $k = q - p$, is used to reduce as many integrals as possible to tadpole integrals, which are known to vanish in dimensional regularization.

To simplify complicated Feynman integrals, we split the gauge propagator (3) into light-cone (LC) and non-light-cone (NLC) propagators, $G_{\mu\nu}^{ab} = \delta^{ab}(G_{\mu\nu}^{LC} + G_{\mu\nu}^{NLC})$, where $G_{\mu\nu}^{LC}$ contains the noncovariant vector n_μ , while $G_{\mu\nu}^{NLC}$ contains only covariant parts:

$$\begin{aligned} G_{\mu\nu}^{ab} &= \delta^{ab}(G_{\mu\nu}^{LC} + G_{\mu\nu}^{NLC}), \\ G_{\mu\nu}^{LC}(q) &= \frac{i}{q^2 + i\epsilon} \left(\frac{q_\mu n_\nu + q_\nu n_\mu}{q \cdot n} \right), \\ G_{\mu\nu}^{NLC}(q) &= -\frac{i}{q^2 + i\epsilon} g_{\mu\nu}. \end{aligned} \tag{13}$$

Finally, in order to handle the vast number of terms in the intermediate stages of the calculation, we employed the program MAPLE, with the add-on package HIP-MAPLE, which allowed us to manage simple operations on large expressions, such as permutations of indices, additions, etc. The main steps involved in the computation of the four-point function may be summarized as follows.

- (i) The Feynman integrals corresponding to the box diagram (Fig. 4), lynx diagram (Fig. 10) and fish diagram (Fig. 15) are written down, and the propagators split according to Eqs. (13), generating 28 major “subdiagrams”.
- (ii) After simplification, each integral in the 28 “subdiagrams” is identified as belonging to one of 44 classes of typical integrals, $[I_{\{a\}}^{\{\mu\}}(\{p\})]_i$, where $\{\mu\}$ indicates the relevant set of Lorentz indices, $\{a\}$ the set of colour indices, $\{p\}$ the set of (arbitrary) external momenta and where $i = 1, \dots, 44$.
- (iii) The UV divergent bit of each of the 44 classes of integrals is evaluated by hand, for general external momenta. The results are fed into the symbolic manipulation program MAPLE, with the add-on package HIP-MAPLE, which greatly simplifies algebraic manipulations of four-vectors. Unfortunately, HIP-MAPLE is unsupported and will not work, without significant revisions, with MAPLE version three or higher.
- (iv) The integrated results of each “subdiagram” are then entered into the computer. The ability of MAPLE to easily substitute specific sets of external momenta and indices into the various integrals is invaluable at this stage.
- (v) The complete expression for the UV divergent bit of 1PI the four-point function is obtained by summing the box, lynx and fish diagrams of Section 4, along with their ‘partner’ diagrams which are generated by taking all topologically distinct permutations of external indices and momenta. The integrated results for all “subdiagrams” and ‘partners’ are combined and simplified, yielding the concise final result in Eq. (35).

4 The 1PI Four-Point Function

The 1PI four-point function in light-cone Yang-Mills theory is comprised of three diagrams: the box diagram (Fig. 4), the lynx diagram (Fig. 10) and the fish diagram (Fig. 15). We shall deal with each diagram separately.

To obtain the complete 1PI four-point function, one must include not only the representative diagrams (discussed in this section), but also the diagrams generated by taking all topologically distinct permutations of external indices and momenta. Once the calculations in Sections 4.1, 4.2 and 4.3 have been completed, the final permutations may be readily generated using MAPLE. Accordingly, we shall only present one specific ordering of the external indices.

Before turning to the explicit calculations, it may be helpful to comment briefly on the possible nonlocal structures allowed in the 1PI four-point function. Each noncovariant propagator G^{LC} contributes a factor $[(q-p)\cdot n]^{-1}$. Since the divergent parts of basic one-loop integrals (i.e. those with only a single factor of $[(q-p)\cdot n]^{-1}$) are *local* functions of the external momenta [24], the pole part of an integral with only one noncovariant propagator is local, and we use the separation formula Eq. (12) as many times as necessary to reduce an integral with multiple noncovariant propagators to a sum of basic one-loop integrals. Furthermore, each application of the separation formula introduces one nonlocal factor $(p_i\cdot n)^{-1}$ in the external momenta p_i , and these are the only non-polynomial factors. Dimensional analysis of the fish, lynx and box integrals Eqs. (15), (23) and (30), reveals that the 1PI four-point function has units of $[p]^0[n]^0[n^*]^0$, so we can tell that, for the fish diagram, the integrated expression can contain only factors of the form

$$f_0^{u_1 u_2 u_3 u_4}, \frac{f_1^{u_1 u_2 u_3 u_4}}{p\cdot n}, \frac{f_2^{u_1 u_2 u_3 u_4}}{(p\cdot n)(k\cdot n)}, \quad (14)$$

where the subscripts 0, 1, 2 indicate the power of momentum in the expression f ; the poles of $(p\cdot n)^{-1}$ are treated according to the n_μ^* -prescription and colour indices have been omitted. In the case of the lynx diagram, an additional factor of the form

$$\frac{f_3^{u_1 u_2 u_3 u_4}}{(p\cdot n)(k\cdot n)(q\cdot n)}$$

can occur, along with those listed above, while in the box diagram a fourth factor,

$$\frac{f_4^{u_1 u_2 u_3 u_4}}{(p\cdot n)(k\cdot n)(q\cdot n)(r\cdot n)},$$

may also appear.

4.1 Box Diagrams

The complete pole part of the box diagram, shown in Fig. 4 is difficult to calculate by virtue of the sheer number of Feynman integrals. It leads to the following expression:

$$\begin{aligned}
 J^{box} = & \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} G_{\mu\nu}(q) V_{a_1 a h}^{u_1 \mu \tau}(p_1, q, q + p_4) \right. \\
 & \delta^{cd} G_{\alpha\beta}(q + p_2) V_{a_2 c b}^{u_2 \alpha \nu}(p_2, -q - p_2, q) \\
 & \delta^{ef} G_{\rho\sigma}(q + p_2 + p_3) \\
 & V_{a_3 e d}^{u_3 \rho \beta}(p_3, -q - p_2 - p_3, q + p_2) \\
 & \delta^{gh} G_{\eta\tau}(q + p_2 + p_3 + p_4) \\
 & \left. V_{a_4 g f}^{u_4 \eta \sigma}(p_4, -q - p_2 - p_3 - p_4, q + p_2 + p_3) \right\} \\
 & \delta^{2\omega}(p_1 + p_2 + p_3 + p_4).
 \end{aligned} \tag{15}$$

Fig. 4. *Complete Box Diagram*

With the decomposition given in Eq. (13), the complete box diagram breaks down into 16 “subdiagrams”, each having only one factor of G^{LC} , or G^{NLC} , along any internal line. Several of the “subdiagrams” are related to each other by permutations of the triplet of external indices and momenta, (a_i, u_i, p_i) , $i = 1, 2, 3, 4$ (see Eq. (18)).

The simplest “subdiagram” (Fig. 5) contains *no* noncovariant terms G^{LC} , which severely restricts the possible tensor structures appearing in the integrated result. The integral corresponding to this subdiagram has the form

$$\begin{aligned}
J_0^{box} = & \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} G_{\mu\nu}^{NLC}(q) V_{a_1 ah}^{u_1 \mu \tau}(p_1, q, q + p_4) \right. \\
& \delta^{cd} G_{\alpha\beta}^{NLC}(q + p_2) V_{a_2 cb}^{u_2 \alpha \nu}(p_2, -q - p_2, q) \\
& \delta^{ef} G_{\rho\sigma}^{NLC}(q + p_2 + p_3) \\
& V_{a_3 ed}^{u_3 \rho \beta}(p_3, -q - p_2 - p_3, q + p_2) \\
& \delta^{gh} G_{\eta\tau}^{NLC}(q + p_2 + p_3 + p_4) \\
& \left. V_{a_4 gf}^{u_4 \eta \sigma}(p_4, -q - p_2 - p_3 - p_4, q + p_2 + p_3) \right\} \\
& \delta^{2\omega}(p_1 + p_2 + p_3 + p_4);
\end{aligned} \tag{16}$$

and yields the simple expression

Fig. 5. *Box Diagram: No Noncovariant Propagators*

$$\begin{aligned}
J_0^{box} = & \frac{\bar{I} f^{a_1 ab} f^{a_2 bc} f^{a_3 cd} f^{a_4 da}}{12} \left\{ 47 [g_{u_3 u_4} g_{u_1 u_2} + g_{u_2 u_3} g_{u_1 u_4}] \right. \\
& \left. + 17 g_{u_1 u_3} g_{u_2 u_4} \right\},
\end{aligned} \tag{17}$$

where $\bar{I} = i\pi^2/(2 - \omega)$.

For “subdiagrams” with one or more G^{LC} factors, the integrated expressions become increasingly complicated, often containing hundreds of individual terms. To see this, consider first the set of diagrams (Fig. 6) including precisely *one* noncovariant propagator $G_{\mu\nu}^{LC}$, which leads to the formula

$$\begin{aligned}
J_1^{box} = & \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} \delta^{gh} G_{\mu\nu}^{LC}(q) V_{a_1 ah}^{u_1 \mu \tau}(p_1, q, q + p_4) \right. \\
& G_{\alpha\beta}^{NLC}(q + p_2) V_{a_2 cb}^{u_2 \alpha \nu}(p_2, -q - p_2, q) \\
& \left. G_{\rho\sigma}^{NLC}(q + p_2 + p_3) \right\}
\end{aligned} \tag{18}$$

$$\begin{aligned}
& V_{a_3 e d}^{u_3 \rho \beta}(p_3, -q - p_2 - p_3, q + p_2) \\
& G_{\eta \tau}^{NLC}(q + p_2 + p_3 + p_4) \\
& V_{a_4 g f}^{u_4 \eta \sigma}(p_4, -q - p_2 - p_3 - p_4, q + p_2 + p_3) \\
& + (1 \rightarrow 2, 2 \rightarrow 3, 3 \rightarrow 4, 4 \rightarrow 1) \\
& + (1 \rightarrow 3, 2 \rightarrow 4, 3 \rightarrow 1, 4 \rightarrow 2) \\
& + (1 \rightarrow 4, 2 \rightarrow 1, 3 \rightarrow 2, 4 \rightarrow 3) \Big\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4);
\end{aligned}$$

here, $(1 \rightarrow 2)$ indicates the exchange of both external indices and momenta;

Fig. 6. *Box Diagrams: One Noncovariant Propagator*

for example: $a_1 \rightarrow a_2, u_1 \rightarrow u_2, p_1 \rightarrow p_2$, and so on. Although all four of these “subdiagrams” are related by symmetry transformations, the possibility of errors in the calculation makes it advisable to compute explicitly at least two of the “subdiagrams”. Evaluation of the integrals in Eq. (18) leads to several hundred terms, but fortuitous cancellation produces the manageable expression

$$\begin{aligned}
J_1^{box} = & \frac{\overline{I} f^{a_1 ab} f^{a_2 bc} f^{a_3 cd} f^{a_4 da}}{n \cdot n^*} \\
& \left\{ -4 \left[n_{u_1} n_{u_4}^* n_{u_3}^* n_{u_2} + n_{u_3} n_{u_1}^* n_{u_4}^* n_{u_2} \right. \right. \\
& \quad + n_{u_1} n_{u_4}^* n_{u_2}^* n_{u_3} + n_{u_4} n_{u_1}^* n_{u_2}^* n_{u_3} \\
& \quad + n_{u_4} n_{u_1}^* n_{u_3}^* n_{u_2} + n_{u_4} n_{u_2}^* n_{u_3}^* n_{u_1} \left. \right] \\
& + 4(n \cdot n^*) \left[n_{u_4} n_{u_3}^* g_{u_1 u_2} + n_{u_1} n_{u_4}^* g_{u_2 u_3} \right. \\
& \quad + n_{u_1} n_{u_2}^* g_{u_3 u_4} + n_{u_4} n_{u_1}^* g_{u_2 u_3} \\
& \quad + n_{u_3} n_{u_4}^* g_{u_1 u_2} + n_{u_2} n_{u_1}^* g_{u_3 u_4} \\
& \quad + n_{u_2} n_{u_3}^* g_{u_1 u_4} + n_{u_3} n_{u_2}^* g_{u_1 u_4} \left. \right] \\
& + 6(n \cdot n^*) \left[n_{u_1} n_{u_3}^* g_{u_2 u_4} + n_{u_2} n_{u_4}^* g_{u_1 u_3} \right. \\
& \quad + n_{u_4} n_{u_2}^* g_{u_1 u_3} + n_{u_3} n_{u_1}^* g_{u_2 u_4} \left. \right] \\
& - \frac{25}{3} (n \cdot n^*)^2 \left[g_{u_1 u_2} g_{u_3 u_4} + g_{u_2 u_3} g_{u_1 u_4} \right] \\
& \left. - \frac{13}{3} (n \cdot n^*)^2 \left[g_{u_1 u_3} g_{u_2 u_4} \right] \right\}.
\end{aligned} \tag{19}$$

With the introduction of the single $G^{LC}(q)$ factor, we already begin to see the emergence of noncovariant terms. Of course, there are no nonlocal terms, since the separation formula Eq. (12) has not been required as yet.

The set of “subdiagrams” containing *two* G^{LC} factors (Fig. 7) is represented by J_2^{box} , where

$$\begin{aligned}
J_2^{box} = & \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} \delta^{gh} G_{\mu\nu}^{LC}(q) \right. \\
& V_{a_1 ah}^{u_1 \mu \tau}(p_1, q, q + p_4) \\
& G_{\alpha\beta}^{LC}(q + p_2) V_{a_2 cb}^{u_2 \alpha \nu}(p_2, -q - p_2, q) \\
& G_{\rho\sigma}^{NLC}(q + p_2 + p_3) \\
& V_{a_3 ed}^{u_3 \rho \beta}(p_3, -q - p_2 - p_3, q + p_2) \\
& G_{\eta\tau}^{NLC}(q + p_2 + p_3 + p_4) \\
& V_{a_4 gf}^{u_4 \eta \sigma}(p_4, -q - p_2 - p_3 - p_4, q + p_2 + p_3) \\
& + (1 \rightarrow 2, 2 \rightarrow 3, 3 \rightarrow 4, 4 \rightarrow 1) \\
& + (1 \rightarrow 3, 2 \rightarrow 4, 3 \rightarrow 1, 4 \rightarrow 2) \\
& \left. + (1 \rightarrow 4, 2 \rightarrow 1, 3 \rightarrow 2, 4 \rightarrow 3) \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4) \\
& + \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} \delta^{gh} G_{\mu\nu}^{LC}(q) V_{a_1 ah}^{u_1 \mu \tau}(p_1, q, q + p_4) \right. \\
& G_{\alpha\beta}^{NLC}(q + p_2) V_{a_2 cb}^{u_2 \alpha \nu}(p_2, -q - p_2, q) \\
& G_{\rho\sigma}^{LC}(q + p_2 + p_3)
\end{aligned} \tag{20}$$

$$\begin{aligned}
& V_{a_3ed}^{u_3\rho\beta}(p_3, -q - p_2 - p_3, q + p_2) \\
& G_{\eta\tau}^{NLC}(q + p_2 + p_3 + p_4) \\
& V_{a_4gf}^{u_4\eta\sigma}(p_4, -q - p_2 - p_3 - p_4, q + p_2 + p_3) \\
& + (1 \rightarrow 2, 2 \rightarrow 3, 3 \rightarrow 4, 4 \rightarrow 1) \Big\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4).
\end{aligned}$$

Evaluation of Eq. (20) yields the expression (38) in Appendix A.

The next contribution to the complete box comes from “subdiagrams” containing three noncovariant propagator factors (Fig. 8), and has the unintegrated form

$$\begin{aligned}
J_3^{box} = \Big\{ & \int \frac{d^{2\omega}q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} \delta^{gh} G_{\mu\nu}^{LC}(q) V_{a_1ah}^{u_1\mu\tau}(p_1, q, q + p_4) \\
& G_{\alpha\beta}^{LC}(q + p_2) V_{a_2cb}^{u_2\alpha\nu}(p_2, -q - p_2, q) \\
& G_{\rho\sigma}^{LC}(q + p_2 + p_3) V_{a_3ed}^{u_3\rho\beta}(p_3, -q - p_2 - p_3, q + p_2) \\
& G_{\eta\tau}^{NLC}(q + p_2 + p_3 + p_4) \\
& V_{a_4gf}^{u_4\eta\sigma}(p_4, -q - p_2 - p_3 - p_4, q + p_2 + p_3) \\
& + (1 \rightarrow 2, 2 \rightarrow 3, 3 \rightarrow 4, 4 \rightarrow 1) \\
& + (1 \rightarrow 3, 2 \rightarrow 4, 3 \rightarrow 1, 4 \rightarrow 2) \\
& + (1 \rightarrow 4, 2 \rightarrow 1, 3 \rightarrow 2, 4 \rightarrow 3) \Big\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4).
\end{aligned} \tag{21}$$

We shall make no attempt to state the pole part of the integrated result of Eq. (21), consisting as it does of some 653 terms. Fortunately, the UV contribution to J_3^{box} is cancelled in its entirety by the corresponding terms, both in its symmetry partners, and in J_3^{lynx} (see below). In fact, it will turn out that this entire pole part of the box diagram is cancelled in the complete 1PI one-loop four-point function.

The last contribution to the complete box comes from the diagram with four internal noncovariant propagators G^{LC} (Fig. 9); the associated integral reads

$$\begin{aligned}
J_4^{box} = \Big\{ & \int \frac{d^{2\omega}q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} \delta^{gh} G_{\mu\nu}^{LC}(q) V_{a_1ah}^{u_1\mu\tau}(p_1, q, q + p_4) \\
& G_{\alpha\beta}^{LC}(q + p_2) V_{a_2cb}^{u_2\alpha\nu}(p_2, -q - p_2, q) \\
& G_{\rho\sigma}^{LC}(q + p_2 + p_3) \\
& V_{a_3ed}^{u_3\rho\beta}(p_3, -q - p_2 - p_3, q + p_2) \\
& G_{\eta\tau}^{LC}(q + p_2 + p_3 + p_4) \\
& V_{a_4gf}^{u_4\eta\sigma}(p_4, -q - p_2 - p_3 - p_4, q + p_2 + p_3) \Big\}
\end{aligned} \tag{22}$$

$$\delta^{2\omega}(p_1 + p_2 + p_3 + p_4).$$

Once again, the intermediate answer from the integral (22) is too unwieldy (611 individual terms) and will not be shown explicitly.

Fig. 7. *Box Diagrams: Two Noncovariant Propagators*

Fig. 8. *Box Diagrams: Three Noncovariant Propagators*

Fig. 9. *Box Diagram: Four Noncovariant Propagators*

4.2 Lynx Diagrams

In this section, we shall discuss the contributions from the complete lynx diagram, Fig. 10, quoting several intermediate expressions. We notice that, in

view of the structure of the bare four-gluon vertex (8), all lynx “subdiagrams” will be symmetric with respect to the following interchange: $a_1 \leftrightarrow a_4, u_1 \leftrightarrow u_4, p_1 \leftrightarrow p_4$. Thus,

$$J^{lynx} = \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} \right. \quad (23)$$

$$G_{\mu\nu}(q) V_{a_2 bc}^{u_2 \nu \alpha}(p_2, q, -q - p_2)$$

$$G_{\alpha\beta}(q + p_2) V_{a_3 de}^{u_3 \beta \rho}(p_3, q + p_2, -q - p_3)$$

$$\left. G_{\rho\sigma}(q + p_2 + p_3) V_{a_1 a_4 fa}^{u_1 u_4 \sigma \mu} \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4).$$

Fig. 10. *Complete Lynx Diagram*

The propagators $G_{\gamma\delta}$ are again split according to Eq. (13), giving eight lynx “subdiagrams”, the simplest being the diagram with *no* noncovariant factors (Fig. 11), namely

$$J_0^{lynx} = \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} \right. \quad (24)$$

$$G_{\mu\nu}^{NLC}(q) V_{a_2 bc}^{u_2 \nu \alpha}(p_2, q, -q - p_2)$$

$$G_{\alpha\beta}^{NLC}(q + p_2) V_{a_3 de}^{u_3 \beta \rho}(p_3, q + p_2, -q - p_3)$$

$$\left. G_{\rho\sigma}^{NLC}(q + p_2 + p_3) V_{a_1 a_4 fa}^{u_1 u_4 \sigma \mu} \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4),$$

which leads to the simple expression,

Fig. 11. *Lynx Diagram: No Noncovariant Propagators*

$$\begin{aligned}
J_0^{lynx} = & -\frac{\bar{I}}{4} \left\{ f^{a_1 ab} f^{a_2 bc} f^{a_3 cd} f^{a_4 da} (2 g_{u_1 u_2} g_{u_3 u_4} + 2 g_{u_1 u_3} g_{u_2 u_4} \right. \\
& \left. + 26 g_{u_1 u_4} g_{u_2 u_3}) \right. \\
& \left. + \frac{N}{2} f^{a_1 a_4 e} f^{a_2 a_3 e} (8 g_{u_1 u_2} g_{u_3 u_4} - 10 g_{u_1 u_3} g_{u_2 u_4} \right. \\
& \left. - 13 g_{u_1 u_4} g_{u_2 u_3}) \right\}. \tag{25}
\end{aligned}$$

Using the same approach as in the reduction of the complete box diagram (Sec. 4.1), we now proceed to compute the remaining sets of lynx “subdiagrams”, containing, respectively a single G^{LC} propagator, and two and three G^{LC} propagators. For *one* G^{LC} propagator, we get the three lynx “subdiagrams” depicted in Fig. 12. The corresponding integral J_1^{lynx} is given by

$$\begin{aligned}
J_1^{lynx} = & \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} G_{\mu\nu}^{LC}(q) V_{a_2 bc}^{u_2 \nu \alpha}(p_2, q, -q - p_2) \right. \\
& G_{\alpha\beta}^{NLC}(q + p_2) V_{a_3 de}^{u_3 \beta \rho}(p_3, q + p_2, -q - p_3) \\
& G_{\rho\sigma}^{NLC}(q + p_2 + p_3) V_{a_1 a_4 fa}^{u_1 u_4 \sigma \mu} \\
& \left. + (1 \rightarrow 4, 2 \rightarrow 3) \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4) \\
& + \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} G_{\mu\nu}^{NLC}(q) V_{a_2 bc}^{u_2 \nu \alpha}(p_2, q, -q - p_2) \right. \\
& G_{\alpha\beta}^{LC}(q + p_2) V_{a_3 de}^{u_3 \beta \rho}(p_3, q + p_2, -q - p_3) \\
& \left. G_{\rho\sigma}^{NLC}(q + p_2 + p_3) V_{a_1 a_4 fa}^{u_1 u_4 \sigma \mu} \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4), \tag{26}
\end{aligned}$$

whose pole part is

Fig. 12. *Lynx Diagrams: One Noncovariant Propagator*

$$\begin{aligned}
J_1^{lynx} = \frac{\bar{I}}{4(n \cdot n^*)^2} \Big\{ & f^{a_1 ab} f^{a_2 bc} f^{a_3 cd} f^{a_4 da} [3(n \cdot n^*)^2 (g_{u_1 u_2} g_{u_3 u_4} + g_{u_1 u_3} g_{u_2 u_4}) \\
& + (n \cdot n^*) (3n_{u_1} n_{u_3}^* g_{u_2 u_4} + 3n_{u_4} n_{u_3}^* g_{u_1 u_2} - 9n_{u_1} n_{u_4}^* g_{u_2 u_3} \\
& - 9n_{u_4} n_{u_1}^* g_{u_2 u_3} - 5n_{u_1} n_{u_2}^* g_{u_3 u_4} - 5n_{u_4} n_{u_2}^* g_{u_1 u_3} \\
& + 4n_{u_3} n_{u_1}^* g_{u_2 u_4} + 4n_{u_3} n_{u_4}^* g_{u_1 u_2} - 2n_{u_2} n_{u_1}^* g_{u_3 u_4} \\
& - 2n_{u_2} n_{u_4}^* g_{u_1 u_3} - 12n_{u_3} n_{u_2}^* g_{u_1 u_4} - 14n_{u_2} n_{u_3}^* g_{u_1 u_4}) \\
& + n_{u_3} n_{u_2}^* n_{u_4}^* n_{u_1} + n_{u_4} n_{u_1}^* n_{u_2}^* n_{u_3} + 3n_{u_4} n_{u_1}^* n_{u_3}^* n_{u_2}
\end{aligned}
\tag{27}$$

$$\begin{aligned}
& + 3 n_{u_2} n_{u_3}^* n_{u_4}^* n_{u_1} + 10 n_{u_4} n_{u_2}^* n_{u_3}^* n_{u_1} - 6 n_{u_3} n_{u_1}^* n_{u_4}^* n_{u_2}] \\
& + \frac{N}{2} f^{a_1 a_4 e} f^{a_2 a_3 e} [(n \cdot n^*)^2 (18 g_{u_1 u_4} g_{u_2 u_3} - 9 g_{u_1 u_4} g_{u_2 u_3} - 3 g_{u_1 u_3} g_{u_2 u_4}) \\
& + (n \cdot n^*) (3 n_{u_4} n_{u_1}^* g_{u_2 u_3} + 6 n_{u_1} n_{u_4}^* g_{u_2 u_3} + 6 n_{u_3} n_{u_2}^* g_{u_1 u_4} \\
& - 2 n_{u_3} n_{u_1}^* g_{u_2 u_4} - 2 n_{u_3} n_{u_4}^* g_{u_1 u_2} + 7 n_{u_2} n_{u_1}^* g_{u_3 u_4} \\
& + 7 n_{u_2} n_{u_3}^* g_{u_1 u_4} + 7 n_{u_4} n_{u_2}^* g_{u_1 u_3} - 5 n_{u_2} n_{u_4}^* g_{u_1 u_3} \\
& - 2 n_{u_1} n_{u_2}^* g_{u_3 u_4} - 18 n_{u_1} n_{u_3}^* g_{u_2 u_4} + 15 n_{u_4} n_{u_3}^* g_{u_1 u_2}) \\
& + 3 n_{u_3} n_{u_1}^* n_{u_4}^* n_{u_2} + 3 n_{u_2} n_{u_3}^* n_{u_4}^* n_{u_1} + 4 n_{u_3} n_{u_2}^* n_{u_4}^* n_{u_1} \\
& - 5 n_{u_4} n_{u_1}^* n_{u_2}^* n_{u_3} - 5 n_{u_4} n_{u_2}^* n_{u_3}^* n_{u_1} - 6 n_{u_4} n_{u_1}^* n_{u_3}^* n_{u_2}] \}.
\end{aligned}$$

The next “subdiagrams” are those containing *two* propagators G^{LC} (Fig. 13), the associated Feynman integral being J_2^{lynx} , where

$$\begin{aligned}
J_2^{lynx} = & \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} G_{\mu\nu}^{LC}(q) V_{a_2 bc}^{u_2 \nu \alpha}(p_2, q, -q - p_2) \right. \\
& G_{\alpha\beta}^{LC}(q + p_2) V_{a_3 de}^{u_3 \beta \rho}(p_3, q + p_2, -q - p_3) \\
& G_{\rho\sigma}^{NLC}(q + p_2 + p_3) V_{a_1 a_4 fa}^{u_1 u_4 \sigma \mu} \\
& \left. + (1 \rightarrow 4, 2 \rightarrow 3) \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4) \\
& + \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} G_{\mu\nu}^{LC}(q) V_{a_2 bc}^{u_2 \nu \alpha}(p_2, q, -q - p_2) \right. \\
& G_{\alpha\beta}^{NLC}(q + p_2) V_{a_3 de}^{u_3 \beta \rho}(p_3, q + p_2, -q - p_3) \\
& \left. G_{\rho\sigma}^{LC}(q + p_2 + p_3) V_{a_1 a_4 fa}^{u_1 u_4 \sigma \mu} \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4).
\end{aligned} \tag{28}$$

The integrated UV divergent contribution to the expression is two pages long and is stated in Appendix A, Eq. (39).

There is a final, single lynx “subdiagram” with *three* noncovariant propagators (Fig. 14), which leads to the formula

$$\begin{aligned}
J_3^{lynx} = & \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} \delta^{ef} G_{\mu\nu}^{LC}(q) V_{a_2 bc}^{u_2 \nu \alpha}(p_2, q, -q - p_2) \right. \\
& G_{\alpha\beta}^{LC}(q + p_2) V_{a_3 de}^{u_3 \beta \rho}(p_3, q + p_2, -q - p_3) \\
& \left. G_{\rho\sigma}^{LC}(q + p_2 + p_3) V_{a_1 a_4 fa}^{u_1 u_4 \sigma \mu} \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4).
\end{aligned} \tag{29}$$

We refrain from listing the integrated answer.

Fig. 13. *Lynx Diagrams: Two Noncovariant Propagators*

4.3 Fish Diagrams

The last, yet easiest, diagram to compute is the complete fish diagram, shown in Fig. 15. It consists of only two four-point vertices and is given by

$$J^{fish} = \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} G_{\mu\nu}(q) V_{a_1 a_4 d a}^{u_1 u_4 \beta \mu} \right. \\ \left. G_{\alpha\beta}(q + p_2 + p_3) V_{a_3 a_2 \nu \alpha}^{u_3 u_2 \nu \alpha} \right\} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4). \quad (30)$$

Fig. 14. *Lynx Diagram: Three Noncovariant Propagators*

Separation of the gauge propagator $G_{\mu\nu}^{ab}$ into covariant and noncovariant prop-

Fig. 15. *Complete Fish Diagram*

agators (as in Eq.(13)) produces four “subdiagrams”. The Feynman integral for the strictly *covariant* fish diagram (Fig. 16) reads

$$\begin{aligned}
J_0^{fish} &= \delta^{2\omega}(p_1 + p_2 + p_3 + p_4) \left\{ \int \frac{d^{2\omega} q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} G_{\mu\nu}^{NLC}(q) V_{a_1 a_4 d a}^{u_1 u_4 \beta \mu} \right. \\
&\quad \left. G_{\alpha\beta}^{NLC}(q + p_2 + p_3) V_{a_3 a_2 b c}^{u_3 u_2 \nu \alpha} \right\} \\
&= \overline{I} \left\{ f^{a_1 ab} f^{a_2 bc} f^{a_3 cd} f^{a_4 da} [g_{u_1 u_2} g_{u_3 u_4} + g_{u_1 u_3} g_{u_2 u_4} \right. \\
&\quad \left. + 4 g_{u_1 u_4} g_{u_2 u_3}] \right\}
\end{aligned} \tag{31}$$

$$+\frac{N}{2}f^{a_1a_4e}f^{a_2a_3e}\left[4g_{u_1u_2}g(u_3,u_4)-5g_{u_1u_3}g_{u_2u_4}-2g_{u_1u_4}g_{u_2u_3}\right]\Big\}.$$

Fig. 16. *Fish Diagram: No Noncovariant Propagators*

There are two fish “subdiagrams” (Fig. 17) having *one* noncovariant factor each, namely

$$J_1^{fish} = \delta^{2\omega}(p_1 + p_2 + p_3 + p_4) \left\{ \int \frac{d^{2\omega}q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} G_{\mu\nu}^{LC}(q) V_{a_1 a_4 c a}^{u_4 u_1 \beta \mu} G_{\alpha\beta}^{NLC}(q + p_2 + p_3) V_{a_3 a_2 b c}^{u_3 u_2 \nu \alpha} + (1 \leftrightarrow 4, 2 \leftrightarrow 3) \right\}. \quad (32)$$

Integration of Eq. (32) yields the following UV contribution

$$J_1^{fish} = -\frac{\bar{I}}{2(n \cdot n^*)} \left\{ [f^{a_1ab} f^{a_2bc} f^{a_3cd} f^{a_4da} g_{u_1u_2} n_{u_3} n_{u_4}^* + g_{u_1u_2} n_{u_4} n_{u_3}^* + g_{u_1u_3} n_{u_2} n_{u_4}^* + g_{u_1u_3} n_{u_4} n_{u_2}^* + g_{u_2u_4} n_{u_3} n_{u_1}^* + g_{u_2u_4} n_{u_1} n_{u_3}^* + g_{u_3u_4} n_{u_1} n_{u_2}^* + g_{u_3u_4} n_{u_2} n_{u_1}^* - 4 g_{u_2u_3} n_{u_1} n_{u_4}^* + g_{u_2u_3} n_{u_4} n_{u_1}^* + g_{u_1u_4} n_{u_3} n_{u_2}^* + g_{u_1u_4} n_{u_2} n_{u_3}^*] + 8(n \cdot n^*) g_{u_1u_4} g_{u_2u_3} \right] + \frac{N}{2} f^{a_1a_4e} f^{a_2a_3e} [2(g_{u_2u_3} n_{u_1} n_{u_4}^* + g_{u_2u_3} n_{u_4} n_{u_1}^* + g_{u_1u_3} n_{u_2} n_{u_4}^* + g_{u_1u_3} n_{u_4} n_{u_2}^* + g_{u_2u_4} n_{u_3} n_{u_1}^* + g_{u_2u_4} n_{u_1} n_{u_3}^* + g_{u_3u_4} n_{u_1} n_{u_2}^* + g_{u_3u_4} n_{u_2} n_{u_1}^* - 4 g_{u_2u_3} n_{u_1} n_{u_4}^* + g_{u_2u_3} n_{u_4} n_{u_1}^* + g_{u_1u_4} n_{u_3} n_{u_2}^* + g_{u_1u_4} n_{u_2} n_{u_3}^*)] \right\} \quad (33)$$

Fig. 17. *Fish Diagrams: One Noncovariant Propagator*

$$\begin{aligned}
& + g_{u_1 u_4} n_{u_3} n_{u_2}^* + g_{u_1 u_4} n_{u_2} n_{u_3}^*) \\
& + 4 (g_{u_1 u_2} n_{u_3} n_{u_4}^* + g_{u_1 u_2} n_{u_4} n_{u_3}^* \\
& + g_{u_3 u_4} n_{u_1} n_{u_2}^* + g_{u_3 u_4} n_{u_2} n_{u_1}^*) \\
& - 5 (g_{u_1 u_3} n_{u_2} n_{u_4}^* + g_{u_1 u_3} n_{u_4} n_{u_2}^* \\
& + g_{u_2 u_4} n_{u_3} n_{u_1}^* + g_{u_2 u_4} n_{u_1} n_{u_3}^*) \\
& - 4 (n \cdot n^*) g_{u_1 u_4} g_{u_2 u_3}] \Big\} \\
& - \frac{\bar{I}}{2 (n \cdot n^*)} \Big\{ f^{a_1 ab} f^{a_2 bc} f^{a_3 cd} f^{a_4 da} (g_{u_1 u_2} n_{u_3} n_{u_4}^* + g_{u_1 u_3} n_{u_2} n_{u_4}^* \\
& + g_{u_1 u_3} n_{u_4} n_{u_2}^* + g_{u_1 u_2} n_{u_4} n_{u_3}^* \\
& + g_{u_2 u_4} n_{u_3} n_{u_1}^* + g_{u_2 u_4} n_{u_1} n_{u_3}^* \\
& + g_{u_3 u_4} n_{u_1} n_{u_2}^* + g_{u_3 u_4} n_{u_2} n_{u_1}^* \\
& - 4 (g_{u_2 u_3} n_{u_1} n_{u_4}^* + g_{u_2 u_3} n_{u_4} n_{u_1}^* \\
& + g_{u_1 u_4} n_{u_3} n_{u_2}^* + 4 g_{u_1 u_4} n_{u_2} n_{u_3}^*) \\
& + 8 (n \cdot n^*) g_{u_1 u_4} g_{u_2 u_3}) \\
& + \frac{N}{2} f^{a_1 a_4 e} f^{a_2 a_3 e} [2 (g_{u_2 u_3} n_{u_1} n_{u_4}^* + g_{u_2 u_3} n_{u_4} n_{u_1}^* \\
& + g_{u_1 u_4} n_{u_3} n_{u_2}^* + g_{u_1 u_4} n_{u_2} n_{u_3}^*) \\
& + 4 (g_{u_1 u_2} n_{u_3} n_{u_4}^* + g_{u_1 u_2} n_{u_4} n_{u_3}^* \\
& + g_{u_3 u_4} n_{u_1} n_{u_2}^* + g_{u_3 u_4} n_{u_2} n_{u_1}^*) \\
& - 5 (g_{u_1 u_3} n_{u_2} n_{u_4}^* + g_{u_1 u_3} n_{u_4} n_{u_2}^* \\
& + g_{u_2 u_4} n_{u_3} n_{u_1}^* + g_{u_2 u_4} n_{u_1} n_{u_3}^*) \\
& - 4 (n \cdot n^*) g_{u_1 u_4} g_{u_2 u_3}] \Big\}.
\end{aligned}$$

There remains a single fish “subdiagram” with *two* noncovariant propagators (cf. Fig. 18), giving the contribution

$$J_2^{fish} = \delta^{2\omega}(p_1 + p_2 + p_3 + p_4) \left\{ \int \frac{d^{2\omega}q}{(2\pi)^{2\omega}} \delta^{ab} \delta^{cd} G_{\mu\nu}^{LC}(q) V_{a_1 a_4 c a}^{u_1 u_4 \beta \mu} G_{\alpha\beta}^{LC}(q + p_2 + p_3) V_{a_3 a_2 b c}^{u_3 u_2 \nu \alpha} \right\}. \quad (34)$$

The answer is again lengthy and has been banished to Appendix A, Eq. (40).

Fig. 18. *Fish Diagram: Two Noncovariant Propagators*

5 Discussion

Before presenting the complete result for the UV divergent contribution to the 1PI four-point function in the light-cone gauge, we shall discuss the constraints on the form of this result.

The presence of nonlocal terms in loop integrals complicates the renormalization procedure appreciably. One could imagine a host of nonlocal expressions that evade the Ward identities. In fact, at first glance, it would seem that there could be an infinite number of such expressions. Fortunately, there are additional constraints on the structure of the non-polynomial divergences in the light-cone gauge which conspire to exclude all but a few of such terms. As a result, only a finite number of nonlocal counterterms is required to renormalize the 1PI functions. Actually, these nonlocal counterterms do not contribute to the complete Green functions and hence they do not affect the observables of the theory [22].

We recall that any light-cone gauge expression can be assigned two degrees of divergence, α and $\alpha_\perp$, where α is the degree with respect to the total large-momentum behaviour of a Feynman integral, while $\alpha_\perp$ is the degree with respect to the transverse large-momentum behaviour. If both α and $\alpha_\perp$ are negative for any diagram and its possible “subdiagrams”, then the corresponding integral will be convergent. To see this, consider the gauge propagator in Eq. (3): since application of the derivative operator $\partial_\perp$ lowers both α and $\alpha_\perp$, repeated use of $\partial_\perp$ on a *divergent* integral will eventually yield a *convergent* one. We conclude, therefore, that the pole part of a subtracted 1PI diagram (i.e. one in which the subdivergences have already been subtracted) will be polynomial in $p_{\perp i}$, the transverse external momenta.

It is furthermore known that in space-like axial gauges ($n^2 < 0$) only *local* divergences are encountered in subtracted 1PI graphs, as demonstrated in Appendix A of [25]. The reasoning is based on the ability to write $q^\mu/n \cdot q$ as $\partial/\partial n_\mu \ln(q \cdot n)$, Wick rotate the resulting integral and apply Weinberg’s theorem [26]. However, this reasoning does not hold in the case of the light-cone gauge. A logarithmic representation of the spurious denominator $(q \cdot n)^{-1}$ implies the principal-value prescription, which is incompatible with a Wick rotation, and hence with the n_μ^* -prescription [4].

Although the n_μ^* -prescription had originally been used to handle the poles of $(q \cdot n)^{-1}$ in the light-cone gauge, the n_μ^* -prescription can be used with any values of n_0 and $\mathbf{n}$, provided that $|\mathbf{n}| \neq 0$. Thus, the space-like limit $n_0 \rightarrow 0$, with $\mathbf{n}$ constant, which yields the space-like axial gauge, is allowed when the n_μ^* -prescription is used. We conclude that the *nonlocal* divergent parts of a subtracted 1PI diagram will become *local*, and perhaps even vanish for $n_0 \rightarrow 0$.

The constraints above are the basis for the prediction of the nonlocal part of 1PI the four-point function by Bassetto, Dalbosco and Soldati [22]. Our explicit calculation yields the same tensor structure as predicted by the authors of Ref [22], along with the local, covariant part of the four-point function:

$$\begin{aligned}
\Gamma_{u_1 u_2 u_3 u_4}^{a_1 a_2 a_3 a_4}(p_1, p_2, p_3, p_4) = & -g^2 \bar{I} \frac{2N}{n \cdot n^*} f^{a_1 a_4 e} f^{a_2 a_3 e} \delta^{2\omega}(p_1 + p_2 + p_3 + p_4) \\
& \left\{ \bar{n}_{\{u_1}^* n_{u_3\}} g_{u_2 u_4} + \bar{n}_{\{u_2}^* n_{u_4\}} g_{u_1 u_3} \right. \\
& - \bar{n}_{\{u_2}^* n_{u_3\}} g_{u_1 u_4} - \bar{n}_{\{u_1}^* n_{u_4\}} g_{u_2 u_3} \\
& + n_{u_1} n_{u_2} g_{u_3 u_4} \frac{n \cdot (p_4 - p_3)}{n \cdot (p_4 + p_3)} \left[\frac{n^* \cdot p_1}{n \cdot p_1} - \frac{n^* \cdot p_2}{n \cdot p_2} \right] \\
& + n_{u_3} n_{u_4} g_{u_1 u_2} \frac{n \cdot (p_2 - p_1)}{n \cdot (p_2 + p_1)} \left[\frac{n^* \cdot p_3}{n \cdot p_3} - \frac{n^* \cdot p_4}{n \cdot p_4} \right] \\
& + 2(n_{u_1} p_{1u_2} - n_{u_2} p_{2u_1}) \frac{n_{u_3} n_{u_4}}{n \cdot (p_3 + p_4)} \left[\frac{n^* \cdot p_4}{n \cdot p_4} - \frac{n^* \cdot p_3}{n \cdot p_3} \right] \\
& + 2(n_{u_3} p_{3u_4} - n_{u_4} p_{4u_3}) \frac{n_{u_1} n_{u_2}}{n \cdot (p_1 + p_2)} \left[\frac{n^* \cdot p_2}{n \cdot p_2} - \frac{n^* \cdot p_1}{n \cdot p_1} \right] \\
& + n_{u_1} n_{u_2} n_{u_3} n_{u_4} \left[\left(\frac{p_2^2}{n \cdot p_2} - \frac{p_1^2}{n \cdot p_1} \right) \frac{1}{n \cdot (p_3 + p_4)} \left(\frac{n^* \cdot p_4}{n \cdot p_4} - \frac{n^* \cdot p_3}{n \cdot p_3} \right) \right. \\
& + \left. \left(\frac{p_4^2}{n \cdot p_4} - \frac{p_3^2}{n \cdot p_3} \right) \frac{1}{n \cdot (p_1 + p_2)} \left(\frac{n^* \cdot p_2}{n \cdot p_2} - \frac{n^* \cdot p_1}{n \cdot p_1} \right) \right] \Big\} \\
& + (2 \rightarrow 3, 3 \rightarrow 4, 4 \rightarrow 2) \\
& + (2 \leftrightarrow 3) \\
& + \frac{22\bar{I}}{3} \left\{ g_{u_1 u_2} g_{u_3 u_4} \left(f^{a_1 a_4 e} f^{a_2 a_3 e} - f^{a_1 a_3 e} f^{a_4 a_2 e} \right) \right. \\
& + g_{u_1 u_3} g_{u_2 u_4} \left(f^{a_1 a_2 e} f^{a_3 a_4 e} - f^{a_1 a_4 e} f^{a_2 a_3 e} \right) \\
& + \left. g_{u_1 u_4} g_{u_2 u_3} \left(f^{a_1 a_3 e} f^{a_4 a_2 e} - f^{a_1 a_2 e} f^{a_3 a_4 e} \right) \right\},
\end{aligned} \tag{35}$$

where $\bar{n}_{u_i}^* = n_{u_i}^* - n_{u_i} n^* \cdot p_i / n \cdot p_i$.

As expected, all terms are polynomial in $p_{\perp i}$, since the only non-polynomial factors are of the form $(p \cdot n)^{-1} = (p_{\parallel} \cdot n)^{-1}$. Moreover, in the limit $n_0 \rightarrow 0$ all terms become *local*, since

$$\left. \frac{n^* \cdot p}{n \cdot p} \right|_{n_0 \rightarrow 0} = -1. \tag{36}$$

Finally, the Ward identity

$$ip_1^{u_1} \Gamma_{u_1 u_2 u_3 u_4}^{a_1 a_2 a_3 a_4}(p_1, p_2, p_3, p_4) = -g f^{a_1 a_2 e} \Gamma_{u_2 u_3 u_4}^{a_3 a_4 e}(-p_3 - p_4, p_3, p_4) \tag{37}$$

$$\begin{aligned}
& -g f^{a_1 a_3 e} \Gamma_{u_3 u_4 u_2}^{a_4 a_2 e}(-p_4 - p_2, p_4, p_2) \\
& -g f^{a_1 a_4 e} \Gamma_{u_4 u_2 u_3}^{a_2 a_3 e}(-p_2 - p_3, p_2, p_3)
\end{aligned}$$

has been explicitly verified including the covariant parts and the relative weights, by using the 1PI three-point function presented in [27].

It may be interesting to note that, although the colour factor $f^{a_1 ab} f^{a_2 bc} f^{a_3 cd} f^{a_4 da}$ and its permuted variations occur throughout the intermediate stages of calculation (in fact, these are the only colour factors that appear in the box diagrams), none of these terms survive in the final result (35).

Appendix A: Intermediate Results

In this appendix we give some of the longer intermediate results of our box, lynx and fish diagram calculations.

1). J_2^{box} , the integrated result of (20):

$$\begin{aligned}
J_2^{box} = & \bar{I} f^{a_1 ab} f^{a_2 bc} f^{a_3 cd} f^{a_4 da} \left\{ \frac{1}{12} [13 g_{u_2 u_4} g_{u_1 u_3} + 4 (g_{u_3 u_4} g_{u_1 u_2} \right. \\
& \left. + g_{u_2 u_3} g_{u_1 u_4})] \right. \\
& - \frac{5 n_{u_1}}{(n \cdot n^*) n \cdot (p_2 + p_3 + p_4)} [g_{u_2 u_3} n_{u_4} (n^* \cdot p_2) + g_{u_2 u_3} n_{u_4} (n^* \cdot p_3) \\

Acknowledgement

We should like to acknowledge E. Yehudai for his software package HIP-MAPLE, which was an invaluable tool for our work. One of us (C.P.M.) would like to thank the Natural Sciences and Engineering Research Council (NSERC) of Canada, and CICYT for financial support. The second author gratefully acknowledges financial support in the form of a scholarship from NSERC. This research was supported in part by NSERC of Canada under Grant No. A 8063.
